#### **ABSTRACT**

#### **Sentiment Analysis from Emotions Using Turkish Dataset**

Ece Nur BALKAN

Department of Computer Engineering
Supervisor Asst. Prof. Dr. MÜMİNE KAYA KELEŞ
June 2023

The aim of this thesis is to develop a system to automatically classify and analyze emotional content in text data using sentiment analysis methods. Sentiment analysis is a natural language processing method used to identify emotional tone in text data and categorize texts into emotional categories such as positive, negative, or neutral. In this study, we included 6 emotions. These; 'positive', 'negative', 'neutral', 'happiness', 'fear', 'sadness'. For this process, the machine learning model and the Bert model were tested and the best results were tried to be obtained. A total of 6000 data sets were studied on the Türkiye data set. There are 1000 datasets for each emotion. Of these, 800 were used for learning and 200 for testing. Our total test dataset is 1200 and our learning dataset is 4800. The first 6 will be machine learning and the top 3 will be vectorized and embedded in the site. These 6 models are: KNN,NBM,RF,DT,SVM,LR. Results For this, the F-Mesaure and RMSE values will be taken into account. In addition, accuracy, precision, recall values will be examined.

**Keywords:** sentiment analysis, natural language processing, machine learning, bert modelling.

## **ACKNOWLEDGEMENTS**

I would like to thank my consultant Asst. Prof. Dr. Mümine Kaya Keleş, who always helped and supported me in this thesis journey.

#### 1. INTRODUCTION

#### 1.1. Description of the problem

Nowadays, we do most of our work online. Some of us follow apps instead of shopping, studying online, and going to the movies. We also leave a treasure after each transaction. Comments. When we process them, they become very valuable.[1]As the author mentioned in his article. Unfortunately, 80% of the data on the market is unstructured. Building them is a process. However, as we mentioned in our topic, processing Turkish comments makes our job even more difficult. Since Turkish is an agglutinative language, we cannot say it negatively when we see the word 'not' as in English.

#### 1.2. AIM

Machine learning models and BERTurk model will be examined by using Turkish data set. The results will be compared and the model with the best results will be embedded in the background of the site. The sentences entered on the created site will be analyzed accurately and quickly.

#### 2. SENTIMENT ANALYSIS

#### 2.1. What is sentiment analysis?

Sentiment analysis uses various methods and algorithms to determine how a text document or comment is perceived emotionally. These methods include machine learning, deep learning and natural language processing techniques. Text data can be analyzed by these methods and associated with emotion labels such as positive, negative or neutral. In addition, more detailed analyzes such as the intensity of an emotional text, the weights of the emotional components or the emotional tendencies on a particular subject can be made.

Sentiment analysis plays an important role in many areas. Businesses try to understand the emotional reactions of customers with sentiment analysis in areas such as social media analysis, customer feedback, brand management and marketing strategies. Policy makers can assess the impact of policies by monitoring social media and analyzing public reactions. In the social sciences, sentiment analysis is used to monitor emotional changes in society, understand social

trends, and understand human behavior.

It is also widely used in areas such as sentiment analysis, big data analytics and text mining. It helps people process large amounts of text data more quickly and effectively. It also provides valuable information in many application areas such as customer satisfaction analysis, product reviews, social media analytics, and public reaction monitoring. Sentiment analysis is a tool that helps us better understand people's emotional responses and improve informed decision making.

#### 2.2. Turkish sentiment analysis

Turkish sentiment analysis is a technique used to classify Turkish text data into emotional categories. Turkish sentiment analysis aims to understand and analyze emotional tone by applying natural language processing (NLP) methods and algorithms on Turkish text data.

The following steps can be followed to do sentiment analysis in Turkish:

Data Collection: In order to collect Turkish text data, it is necessary to collect data from appropriate sources (social media, websites, surveys, customer feedback, etc.).

Data Pre-Processing: Pre-processing steps should be applied on the collected Turkish text data. These steps include cleaning up text (removing punctuation, removing unnecessary characters, converting to upper-case letters, etc.), removing stop-words, and identifying root words.

Feature Extraction: It is necessary to extract meaningful features from Turkish text data. In this step, text data is converted into numerical representations using methods such as word selection, word frequency, TF-IDF (Term Frequency-Inverse Document Frequency).

Model Training: A sentiment analysis model is trained using Turkish text data and tags from which feature extraction is performed. This model can be a machine learning algorithm or a deep learning model to identify emotional tones in Turkish texts.

Model Validation and Adjustments: The trained model is tested on the validation dataset and its performance is evaluated. If necessary, model adjustments are made and retested.

Sentiment Analysis Application: The trained and validated model is used to perform sentiment analysis on real-world data. Turkish text data is classified into emotional categories (positive, negative, neutral, etc.) by the trained model.

Turkish sentiment analysis can provide valuable information in areas such as understanding the emotional content of Turkish texts, social media analysis, brand management, customer feedback, marketing strategies and public opinion analysis. By performing sentiment analysis on Turkish texts, it may be possible to understand the emotional expressions specific to the Turkish language and culture and to make effective decisions.

#### 3. LITERATURE REVIEW

#### 3.1. Turkish sentiment classification studies

In the first study in which sentiment analysis was performed for Turkish [16], labeled sentences from Turkish children's tales and the translation of ISEAR [19] dataset were analyzed on 4000 samples in the categories of "joy, sadness, anger and fear". As a result of the study, in which traditional machine learning methods were applied, approximately 80% success was achieved. In another study in Turkish [20], sentiment analysis was conducted on Twitter, one of the social media environments. According to the hashtags used by the users in their posts, as a result of the sentiment analysis using traditional machine learning and classification methods on a total of 6000 tweets in each category, which were collected in Ekman's 6 emotion categories: "fear, anger, disgust, joy, sadness and surprise". 70 achievements have been achieved. In another study, 86% success was achieved as a result of Turkish sentiment analysis [190], which was performed in 7 classes using Naive Bayes. In another study conducted in Turkish [32], a sentiment dictionary was created by using attribute selection and weighting methods over the Turkish sentiment dataset [33], which had 26000 samples previously created by the researchers, and sentiment analysis was carried out with the help of this dictionary. As a result of the feeling analysis made in Ekman feeling categories, approximately 91% success was achieved. In another study, [18] performed sentiment analysis with deep learning algorithms on the TURTED sentiment dataset, which was created from Twitter posts containing keywords belonging to sentiment categories, and achieved 73% success. As can be seen, very few studies have been carried out in the field of Turkish sentiment analysis, and it has been observed that the studies are generally done by emulating text classification studies and methods with a dictionary have also been tried.

while (t < maksimum iterasyon sayısı)
         for p in parçacık
                   p'nin konumunu güncelle (2.20)
          end for
          a, A ve C değerlerini güncelle
         Her parçacığın konumunu ve uzaklığını hesapla
         X_{\alpha}, X_{\beta} ve X_{\delta} değerlerini güncelle
          t=t+1
end while
return X_{\alpha}
```

Figure 1 This is the gray wolf algorithm. The algorithm gave the best results in its study.

#### Historical Development of Sentiment Analysis Studies

Sentiment analysis studies started to be done for English in the early 2000s, as can be seen in Figure 2 [3]. First of all, sentiment analysis studies were carried out with traditional machine learning (DML) methods [3,10,11]. The first sentiment analysis study for Turkish was carried out in 2013 using DME methods [16]. Another study for Turkish using DMR methods was published in 2014 [17]. The success has been increased by adding the attributes obtained from the hiss dictionaries as well as the words as input to the DMI methods [6–9,11]. With the use of deep learning (DL) methods in sentiment analysis in 2017, the prior knowledge obtained from dictionaries has been replaced by word occupants [12,13,14,15]. On the other hand, the creation of a validated and accessible sentiment analysis dataset (TREMO) in Turkish was carried out in 2018 [4]. In 2019, a limited dictionary of sensations was obtained by using the

word association statistics in the TREMO Turkish dataset, and Turkish sentiment analysis was carried out by using it together with the DME methods [5]. The Turkish sentiment analysis approach, on the other hand, could only be done at the end of 2019 [18]. Within the scope of the study with DÖ, the TURTED sentiment dataset consisting of Turkish Twitter posts was created and sentiment analysis was performed for Ekman sentiments. Obtaining more successful results with LL methods than DML methods and dictionary-supported hybrid methods has led to the need to add more prior knowledge to learning. With the pre-trained language model (ODM) approaches aiming to meet this need, the prior knowledge gained through big data has been transferred to deep learning methods.

# 4. RESULTS USING MACHINE LEARNING AND THE BERT MODEL

Machine learning is a field of artificial intelligence that enables computer systems to gain the ability to solve a specific task or problem by automatically learning and experiencing it using predefined data and algorithms. Machine learning focuses on computer programs learning a particular task or problem through data-driven experiences and algorithms without being manually programmed.

Machine learning can perform complex tasks such as discovering patterns, relationships and trends, making predictions, classifying, clustering, building recommendation systems, and making decisions based on large amounts of data. Machine learning algorithms build models based on data and can use these models to perform tasks such as predicting future data or classifying new data.

It uses methods and techniques from fields such as machine learning, statistics, mathematics, data mining, and artificial intelligence. Data preprocessing includes steps such as feature selection, model training, model validation, and model improvement. Machine learning is widely used to solve real-world problems, make data-driven decisions, and improve automation processes.

It has achieved great success in various application areas such as machine learning, voice and image recognition, natural language processing, automated car driving, financial forecasting, medical diagnostics, product recommendations and target marketing. Thanks to machine learning, computers can process complex data sets, recognize patterns and learn in a similar way to humans.

#### 4.1. Properties of the dataset

The data set consists of Turkish characters. There are 6000 data in total. 4800 is the learning data set. 1200 is the test data set.

#### 4.2. Preprocessing Steps

To process text data for natural language processing applications such as sentiment analysis, the following preprocessing steps are typically applied:

Text Cleaning: It is the process of removing unnecessary elements from text data such as unnecessary characters, punctuation marks, numbers or special characters. In this step, special symbols such as HTML tags, links, emojis in the texts can be cleaned.

Tokenization: The process of breaking texts into smaller pieces. Texts are often divided into words or phrases. This means that sentences or paragraphs are segmented as words or symbols.

Upper / Lower Case Conversion: It is the process of converting all letters in the text to uppercase or lowercase letters. This is done to organize the word distribution in the text and to combine different letter cases of the same words.

Removal of Stop Words: It is the removal of commonly used words called grammatical junk words or stop words. Such words are often meaningless and limited in providing information in tasks such as sentiment analysis [2]Author's stopword.txt is used for this step.

{acaba; altı; altmış; ama; ancak; artık; asla; aslında; az; bana; bazen; bazı; bazıları; bazısı; belki; ben; bende; benden; benii; benim; beş; bile; bin; bir; biri; birçoğu; birçok; birçokları; biri; birisi; birlikte; birkaç; birkaçı; birkez; birşey; birşeyi; biz; bizde; bizden; bize; bizi; bizim; böyle; böylece; bu; bu arada; bu yüzden; buarada; buna; bunda; bundan; bunu; bunun; burada; burda; buyüzden; bütün; çoğu; çoğuna; çoğunu; çok; çünkü; da; daha; dahi; de; defa; değil; demek; diğer; diğerleri; diye; doksan; dokuz; dolayı; dört; elbette; elli; en; fakat; falan; felan; filan; gene; gibi; hâlâ; hangi; hangisi; hani; hatta; hem;henüz; hep; hepsi; hepsinde; hepsinden; hepsine; hepsinin; her; her biri; herbiri; herkes; herkese; herkesi; hiç; hiç kimse; hiçbir; hiçbiri; hiçbirine; hiçbirini; hiçkimse; için; içinde; ilk; iki; ile; ise; işte; kaç; kadar; katrilyon; kendi; kendine; kendini; kendisi; kendisine; kez; kırk; ki; kim; kimde; kimden; kime; kimi; kimin; kimisi; kimse; madem; mı; mi; milyar; milyon; mu; mü; nasıl; ne; ne kadar; ne zaman; nekadar; nezaman; neden; nedir; nerde; nerede; nereden; nereye; nesi; neyse; niçin; niye; olan; olarak; on; ona; onda; ondan; onlar; onlara; onlarda; onlardan; onları; onların; onu; onun; orada; otuz; oysa; oysaki; öbürü; ön; önce; ötürü; öyle; rağmen; sana; sanki; sekiz; seksen; sen; sende; senden; seni; senin; siz; sizde; sizden; size; sizi; sizin; son; sonra; sayet; sey; seyde; seyden;

Root Extraction or Lemmatization: It is the process of obtaining the roots or root forms of words. This includes removing changes such as inflections and plurals while keeping the basic meaning of the word. Root extraction and lemmatization can reduce word diversity in the text and increase the consistency of the analysis.

Text Vectorization: It is the process of converting texts into numerical vector representations. This is necessary so that machine learning algorithms can process text data. Techniques such as TfidfVectorizer can create vectors that reflect the frequency and importance of words in texts.

These preprocessing steps are used to represent text data in a more workable and more consistent way. The preprocessing steps can be customized depending on the particular sentiment analysis application and the dataset to be used.

Table 4 NBM

#### 4.3. Which models did we use?

Naive Bayes: Naive Bayes classifier is a probabilistic model used to predict emotional labels of texts. It assumes that the words in the texts are independent and calculates the probabilities of these words between classes.

Support Vector Machines (SVM): Support Vector Machines are a widely used classification method for classifying texts. By converting texts to vector representations, it creates a decision boundary to predict belonging to a particular emotional class.

Decision Trees: Decision trees use a tree structure to predict the emotional classes of texts. Each node represents a division by a particular property and its values. Using the features of the texts, a series of decision structures are created and emotional classes are determined at the end.

#### K-Nearest Neighbor (KNN):

KNN is a simple and popular classification and regression algorithm.

In the case of classification, it uses the k nearest neighbors whose labels are known to classify a data point.

In the case of regression, it uses the mean of the k nearest neighbors to estimate the output of a data point.

KNN is mainly based on distance measurements of data points (usually the Euclidean distance is used).

The user-specified parameter k determines how many neighbors are to be considered.

KNN is a widely used algorithm with its simple and understandable structure.

#### Logistic Regression:

Logistic regression is a linear regression algorithm used in classification problems.

It is used to separate data points into two or more classes.

Logistic regression attempts to classify data points according to a linear decision boundary.

Logistic regression uses the logistic function (sigmoid function) to estimate the output.

Logistic regression generates the probability values of the predictions and classifies by setting a cutoff threshold.

Logistic regression is a widely used algorithm because of its simplicity, interpretability and speed.

#### Random Forest:

A random forest is an ensemble (combination) algorithm created by combining many decision trees.

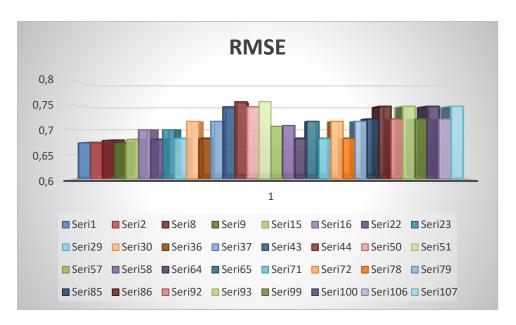

Each tree is trained by random sampling and random feature selection.

The random forest takes an estimate of each tree and determines the result by majority voting or average value.

Random forest is resistant to overfitting and generally provides high performance.

Random forest can be used in both classification and regression problems.

Random forest is a computationally efficient algorithm that can run in parallel on large datasets.

#### 4.3.1. Methods Used

Machine Learning Based Classification Models: These approaches use machine learning algorithms to identify emotional labels of texts. A classification model is trained using a prelabeled dataset and then predictions are made on new texts. For example, algorithms such as Support Vector Machines (SVM), Decision trees, Logistic Regression, Naive Bayes can be used.

Different from Figure 1, it was evaluated on 6 titles. These are 'pozitif', 'negatif', 'nötr', 'hüzün' 'korku', 'mutluluk'.

Models used: KNN, Naive Bayes Multinomial, Random Forest, Decision Table, SVM, LR. Models used on the website, BERTurk, SVM, LR, NBM.

TfidfVectorizer was used for vectorization.

#### 4.3.2 Applications and Libraries Used

Data extraction: beautifulsoup, selenium /jupiter notebook

import SVC,sklearn.model\_selection import train\_test\_split/Google Colab

Site: flask import Flask, render\_template, request,HTML/ Spyerdar

#### 4.4. What performance metrics did we use?

F1-Score (F1-Score): F1-Score is a criterion used to evaluate the performance of classification models. It is the harmonic mean of the precision and recall metrics. The F1-Score tends to minimize both false positives and false negatives of a model. That is, it evaluates the overall performance of the model, taking into account both precision and recall.

Precision: Precision is the rate at which samples that a classification model predicts positively are actually positive. That is, it shows how accurately a model predicts true positives. Precision is important in applications with the goal of minimizing false positives. For example, it is important to have as few false positives as possible in spam filtering applications.

RMSE (Root Mean Square Error): RMSE is an error metric used to measure how far the predictions of a regression model are from the true values. The RMSE is the square root of the mean of the squares of the prediction errors. Smaller RMSE values indicate that the model's predictions are closer to the true values.

Recall: Recall is a metric that shows how accurately a classification model predicts true positives. Recall is important in applications with the goal of minimizing false negatives. For example, it is important to have as few false negatives as possible in disease diagnosis practices.

These metrics are used to measure and evaluate the performance of a model. When assessing the success of the model, it is important to consider the class balance, the characteristics of the dataset, and the intended application. The combination of metrics such as F1-Score, precision, RMSE and recall helps to comprehensively evaluate the performance of the model.

#### 4.5. What is Bert?

BERT (Bidirectional Encoder Representations from Transformers) is a deep learning based language model developed by Google. BERT has had great success in natural language processing (NLP) and has delivered best-in-class results on many NLP tasks.

BERT uses the Transformer architecture and is pre-trained as a general language model for many language processing tasks. Using large amounts of text data, the model learns wordlevel relationships and grammatical patterns. The most important feature of BERT is that it can process text in both directions (forward and backward). This allows him to better understand the meaning of the word and the context in which it is used.

BERTurk is a pre-trained BERT model for use in the Turkish language. It is a BERT model trained with Turkish dataset to understand grammatical patterns and relationships in Turkish texts. BERTurk provides high performance in Turkish language by using sentiment analysis, text classification, word similarity and other NLP tasks.

BERT and BERTurk are very effective and successful models in the field of natural language processing. They stand out for their general language comprehension and performance in text processing tasks.

The use of the BERTurk model is a very long study. On the other hand, this model could not be included because we could not get good results from our own data set.

## 5. SITE FORMATION

The site is connected with the HTML method, which is a basic structure. The spider ide is used for the site creation. The analysis file has been created and links with HTML templates have been added. The site creation phase has been completed using flash in Python. The studies were carried out by embedding the files vectorized with the TDFIDF method into the site.

#### 6. CONCLUSION AND FUTURE WORK

Our study is based on sentiment analysis and its transfer to a site. Our study, which consists of 6000 data in total, is divided into 4800 train and 1200 test data. There are 1000 datasets for each emotion and they are 800 train, 200 test datasets. These are added to the machine learning models by going through certain preprocessing steps. Work started with 6 machine learning models. These are: K - Nearest Neighbor, Decision Tree, Logistic Regression, Random Forest, Supert Vector Machine, Naive Bayes Multinomial. Algorithms with the highest results will be selected. The algorithms with the highest results will be compared with the Bert model. It should not be overlooked that the pre-processing stage is also of great importance. 16 different combinations were applied. These are sub, punctuation, single word, root word combinations. The best results were obtained with the 1110. So alt+punctuation+keyword.

In this study, Support Vector Machine (SVM), Naive Bayes (Multinomial) and Logistic Regression models were selected as machine learning models and compared with the BERT model. The aim of the study is to evaluate the performance of these models in the sentiment analysis task and to obtain the best result.

According to the results obtained, although the SVM model has a high accuracy rate, it worked slower than other models in terms of computation time. The Naive Bayes (Multinomial) model ran fast, but the accuracy rate was slightly lower than the SVM model. The Logistic Regression model, on the other hand, provided a good balance in terms of both computation time and accuracy. The preference of the SVM model for Model Selection is that the RMSE values are higher than the others.

On the other hand, although the BERT model is more complex than other machine learning models, it was expected to have the highest accuracy, but this could not be achieved. This is surprising. Because BERT is a tool that can better understand grammatical patterns and better represent texts. Thus, while it should outperform text-based tasks such as sentiment analysis, it yielded the opposite result. The BERT model has a longer computation time than other models, and this is a factor to consider when working with large datasets. In my own work, the model took 13 hours to train and used most of the computer's CPU.

As a result, in our study, when SVM, Naive Bayes (Multinomial) and Logistic Regression models were compared with the BERT model, it was seen that the BERT model did not

provide the highest accuracy rate and was not successful in sentiment analysis. In addition, considering the computation time and complexity of the model, it seems risky to choose this model in the context of the application. The high F1-Score and RMSE values of the SVM model also enabled this model to be selected. The SVM model and vectors are embedded in the 'Sense Analysis' website.

It cannot be said that our business is completely trouble-free. But it should not be overlooked that there are good lessons in their mistakes. Some notes should be taken from the study. If the size of our dataset was sufficient, artificial neural networks and deep learning would be preferred, which are the most successful in language learning. Even if machine learning is reintroduced, a few changes need to be made. Since the biggest problem in this study is experienced in the data preprocessing phase, ZEMBEREK library should be included for root analysis. For the frequency range, Word2Vect or Doc2Vec can be used. In this way, more successful results can be obtained. On the other hand, easier tagging studies can be done by considering emojis.

It should be known that working with Turkish data is more difficult than languages such as English. It should be known that it complicates our work because it is an agglutinative language. For this reason, it is of great importance that every work done is successful and unsuccessful. Every unsuccessful work will actually lead us to the truth. Further work in the future will take us further in Turkish language processing.
